NYISO Transmission Performance Report – 2003

Introduction

This report summarizes NYISO transmission utilization during 2003 and compares this with transmission use in the previous three years. Data is presented in a general format using histograms, cumulative distribution plots, and box plots. Included are graphical depictions of power flows on:

- NYISO interfaces and OASIS Transmission paths, including all operating interfaces and selected planning interfaces.
- Selected individual transmission lines
- Energy schedules with external Control Areas.

There are also sections on power transfer margins and simultaneously constraining interfaces. The power transfer margins show the difference between the active real time power transfer limit and the actual power flow on the interface. The analysis of simultaneously constraining interfaces tallies the number of hours two or more interfaces were within 100 MW of their respective operating limits. These analyses are included only for NY internal operating interfaces.

The analysis is based on NY historical real time data sampled in 5-minute (nominal) intervals. The power flow values in each of the charts are hourly averages of the scan data. The data is presented in three graphical formats; histograms (frequency bar charts), flow duration curves, and box plots (showing monthly average flows through time).

Since 2002, the analysis of On-Peak vs. Off-Peak transmission flow has been included. This data is presented in two graphical formats: histograms (frequency bar charts) and flow duration curves.

Conclusions

The Open Access Same Time Information System (OASIS) transmission paths have been monitored since 1997. The flow data on these paths are presented in this report for informational purposes only. Schedules and actual power flows between NYISO and external systems vary significantly.

In 2003, NY was exporting about 1% of the time, the same as in 2002 and 2000, about 2% of the time in 2001. The maximum and average NY imports were higher in 2003 than in the previous three years. In July 2003, the average import was greater than 2500MW. The maximum import was greater than 4600 MW in 2003, about 4000 MW in 2002 and 2000, and 3500 MW in 2001.

NY scheduled imports from PJM 96% of the time in 2003; higher than the previous three years;, 87% in 2002, 88% in 2001, and 86% in 2000. During On-Peak hours about 93% of the time in 2003, 77% in 2002, and during Off-Peak hours was 98% of the time, about the same as last year. The maximum scheduled export to PJM was lower than in last 3 years, about 1200 MW, compared to 2400 MW in 2002.

NY actually imported from PJM about 99% of the time in 2003, 92% in 2002, 95% in 2001, and 94% in 2000. In 2003, import during On-Peak and Off-Peak hours were the same; 99% of the time.

The highest maximum and average NY exports to PJM occurred between June and August during the last 4 years. In the summer months of 2003, NY exports to PJM were lower than in 2002, 2001 and 2000.

NY scheduled imports from IMO in 2003 about the same in 2002 but lower than in 2001 and 2000, about 10% of time flow in 2000, 14% in 2001, and 25% in 2002 and 2003. During the On-Peak hours about 40% of the time, 16% of the time during the Off-Peak hours, compare to 35%, and 15% of the time in 2002, respectively.

NY scheduled exports to NE 58% of the time, and imports 42% of the time. NY imported from NE about 52% of time during On-Peak hours and about 28% of the time during Off-Peak. NY imports from NE were highest in April 2003 at 1500 MW, higher than the previous three years, and exports to NE highest in March 2003 at 1500 MW.

In 2003, NY scheduled imports and export with TE were lower than in last 3 years in both magnitude and duration; importing about 55% of time, about 75% during the On-Peak hours and 25% during the Off-Peak hours. Scheduled imports from TE were below 1000 MW about the same as last year, 37% of the time and below 700 MW about the same in 2002, 30% of the time.

Average transmission utilization on most internal NYISO operating interfaces in 2003 was similar to levels observed during the previous three years. In 2003, the Total East, Central East, Moses-South flow duration curves were lower than in last 3 years in both magnitude and duration. Moses South flows were north less than 3% of the time.

The Total East interface was consistently operated near its limit, however because of the black out, the margin to Total East reached to about 5600 MW, and the margin to Sprain Brook-Dunwoodie South reached to above 3800 MW on August 14, 2003. Total East interface was above limit of 5450 MW was lower the last 3 years, about 1 % in 2003, compared to 2% of the time in 2002, 3% in 2001, and 10% in 2000. Sprain Brook- Dunwoodie South interface was above limit of 2450 MW less than 1% in 4 years.

The Dysinger-East, West-Central, UPNY-ConEd, and Sprain Brook/Dunwoodie-South flows duration curves were similar to levels observed in the last 3 years. Plots of the flow duration curves for the PJM East-New York City, LIPA Import, ConEd-LIPA, Dunwoodie-Shore Road, Sprain Brook/Dunwoodie-South, Volney-East flows drop off the chart, and the Ontario

East-Adirondack flow duration curve goes above the chart due to the flows experienced during the blackout of August 14, 2003.

The table below compares minimum flows that occurred 75% of the time (above the lower quartile) and the percent of time the respective flows were within 200 MW of their active limits.

Year	Central East		Total East	
	Flow >75% of the time	% of time within 200 MW of limit	Flow > 75% of the time	% of time within 200 MW of limit
2003	1483MW	17%	3359MW	<1%
2002	1540MW	29%	3486MW	<1%
2001	1827MW	42%	3795MW	<1%
2000	2021 MW	68%	4231 MW	< 1%

Results

The three graphical formats (histograms, flow duration curves, and box plots) present the data in different ways to show statistical distribution and comparisons of flows from year to year. The following describes each of the graphical formats. An explanation of the transfer margin calculation is also included.

Histograms

These show the statistical distribution of flows over the observed operating range for the year. The data is presented for the current year (2003). The values along the ordinate are midpoints of a preselected range. For example, two consecutive midpoints of 300 and 600 represent all the flows with values of $300 \text{ MW} \pm 150$ and $600 \text{ MW} \pm 150$. The length of the bars represents the frequency, or the number of times a flow is within the range around the midpoint.

In the case of unrestricted operation on a facility there would be a random distribution of flows leading to a statistically normal distribution. In practical cases the distribution is skewed in one direction or there may be certain ranges that have "spikes". The flows may skew towards a certain level for several reasons: an economic optimum may exist for a while that inclines the flow to a certain value, an interface or facility may be operating at or near its limit, or a nearby facility may be limited and consequently limits the facility in question.

An example of spikes in the histogram is a transmission line out of service. The line may have a normal distribution of flows from 200 to 600 MW and a large spike at zero representing

the time the facility was out of service. Unfortunately the raw data does not distinguish between O/S conditions or actual zero flow, although the latter is fairly uncommon for most facilities.

Flow Duration Curves

In a continuous monotonically decreasing curve, this shows the percentage of time a facility or interface was operating at or above a certain value in its observed operating range. The graphs include the current year, 2003, and the previous three years (2000, 2001 and 2002). Overlaying the curves for each year gives a visual comparison on how the utilization of the particular facility is changing.

Box Plots

Box and whisker plots give a through time graphic view of statistical distributions of data at each discrete time or time period. The plots in this report include four years of data, the current year (2003) and the previous three years (2000-2002). The time axis (abscissa) represents each month during the four-year analysis period. The boxes and whiskers represent all the flows observed during a month.

The green horizontal line on the plots in this report connects the monthly average (MW flow) values. The "box" represents the inter-quartile range, in which 50% of the data values lie. The bar in the middle of the box is the (statistical) median. The median cuts the box into two parts; each contains 25% of the data values. The long green vertical lines extending from the boxes, whiskers, represent the higher and lower 25% (quartiles) of the data values. These whiskers extend to the absolute minimum and maximum value observed in the respective time period (1 month in this case). The tick marks on the whiskers are placed at distance not exceeding 1.5 times the length of the box (inter-quartile range), from each edge of the box. This highlights extreme minimums and maximums that may have occurred and separates the extremes from the rest of the data values.

Transfer Margins

A supplementary section is included showing transfer margins on NYPP operating interfaces. The transfer margin is the MW transfer capability remaining from the instantaneous flow to the active transfer limit. These values are calculated by taking the active directional transfer limit and subtracting the real time flow at each (5 minute) scan.

$$\text{Transfer Margin} = \text{Transfer Limit}_{\text{directional}} - \text{ABS}(\text{Actual Flow})$$

The transfer margin is generally a positive number. A negative number would represent flow exceeding the transfer limit. The plotted values are the hourly averages of the calculated differences. The transfer margins are presented in the same format as the flows and schedules (i.e., histograms, duration curves, and box plots).

It is important to keep in mind that the bars on the histograms represent the frequency of occurrence in a range around the midpoint. Using the Total East margin as an example, the

histogram 2003 has midpoints at 600 and 1000 MW. The bar at 1000 means that Total East was operating within 400 MW of its active limit 2.37% of the time during 2003. The bar at 2200 means that Total East was operating within 400 MW of its active limit 19.81% of the time, at levels potentially up to 2400 MW limit 44.17% during 2003. Except in the case of unusually high overloads on an interface (i.e., spikes, contingencies), the margins are generally zero or greater.

There are two sets of charts for Central East Transfer Margins: one for pre-contingency flows, and the second for post-contingency flow and limits. The Central East post-contingency transfer margin is calculated by taking the minimum margin, or difference, of the three post contingency voltage collapse limits and their respectively calculated post contingency flows.

Interfaces Simultaneously Constraining Transfers

The table in Appendix D summarizes the combinations of interfaces as they were simultaneously constraining during 2000, 2001, 2002 and 2003. Interfaces were considered constraining if the actual flow was within 100 MW of the respective interface's limit. This limit was the active transfer limit in the real-time system at the time of the sampling.

The results are summarized as hourly values derived from 5-minute real time samples. In the four year time period sampled, there were 80 unique combinations of NY operating interfaces that were constraining at various times. These combinations range from two to five interfaces at a time. Some of the combinations are recurring over each of the years, others occurred in only one year. Several combinations occurred only once.

For the circumstances analyzed, two or more interfaces were constraining from 9% to 22% of the time in a given year between 2000 and 2003. The Central East/Central East net PC (post-contingency) appeared 2% to 16% of the time. Most of the rest of the simultaneous constraints occurred 7% of the time or less. This indicates the total percentage is an accumulation of many combinations, that may occur for a variety of reasons, rather than a few that may occur for some common phenomenon. Central East and Total East are closely related. If this combination is removed, the percentages are still significant. In 2003, the Central East/Total East combination was not constraining. During the last 2 years, the annual totals with and without the Total East/Central East combination are the same 17% in 2003, and 9% in 2002. The annual totals with and without the Total East/Central East combination are summarized in the table below.

Year	All Combinations		Central East/Total East Excluded	
	Hours	Percent of Year	Hours	Percent of Year
2000	1921	22.0%	1874	21.4%
2001	1252	14.0%	1243	14.0%
2002	819	9.0%	819	9.0%
2003	1462	17.0%	1462	17.0%

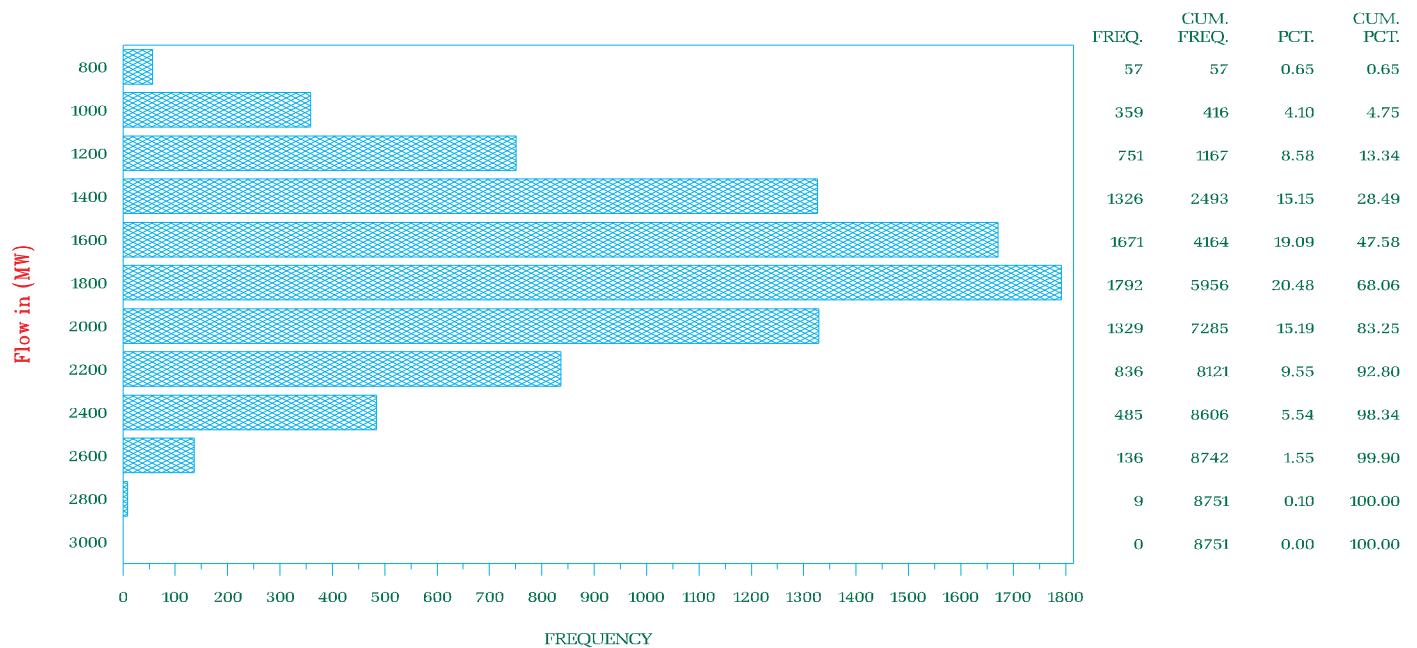

Further restrictions are also likely by virtue of individual line constraints. The analysis presented here only used interface flow related data. Interfaces, or Transmission Paths (to use the new terminology) are often implicitly limited by a single element for some contingency (e.g., the loss of one Leeds-Pleasant Valley 345 kV circuit on the parallel Leeds-Pleasant Valley 345 kV circuit). This contingency implicitly limits both Central East and UPNY-Con Ed. This is not reflected as an explicit interface limit and outside the context of this analysis. The overall trend from 2000 to 2003 is decreased simultaneous interface limits; this may be the result of Central East, by itself, being more constraining.
